Integration Systems let you define the business or source systems that DataX works with, such as a core banking platform, CRM, or payroll system. In practice, they help you keep the right database connectors and the right PII matching rules together.

Overview

Use Integration Systems when you want to:

- group one or more database connectors under a single named system
- control which systems appear in Data Discovery after a connector is selected
- scope PII matching patterns to a specific source system

Where To Access

Go to **Admin > DataX > Integration Systems**.

Before You Start

Have the following ready:

- a clear short name for the source system
- a descriptive full name that other admins will recognise
- the database connector or connectors that belong to that system

Key Elements

List Page

The list page shows one row per integration system and supports search, sorting, and the standard actions available to your role.

Column	Meaning
Integration System ID	The internal identifier for the system
System Name	The short name used throughout the product
System Description	A longer business-friendly label for the same system

Typical actions on this page are:

- **Create** a new system
- **Edit** an existing system
- **Clone** a system to use as a starting point
- **Delete** a system you no longer need

Form Fields

When you create or edit a record, complete these fields:

Field	How To Use It
System Name	Enter a short, stable name such as <code>CBS</code> , <code>CRM</code> , or <code>PAYROLL</code> .
Full Name	Enter a fuller description such as <code>Core Banking System</code> or <code>Customer Relationship Management</code> .
Data Connectors	Select one or more existing database connectors that belong to this system.

Only connectors that are not already linked to another Integration System are available for selection. This keeps Data Discovery from showing competing systems for the same connector.

Common Tasks

Create An Integration System

To create a system:

1. Click **Create Integration System**.
2. Enter the system name and full name.
3. Select the related data connectors.
4. Save the record.

Edit An Integration System

To update a system:

1. Open the system from the list.
2. Change the name fields or connector selection as needed.
3. Save the record.

NOTE

The connector links matter for Data Discovery. After a user selects a database connector, Data Discovery only offers integration systems that are linked to that connector.

NOTE

If a connector is already linked to another Integration System, remove that mapping first before assigning it to a different system.

Clone A System

Use **Clone** when you want to create a similar system without starting from scratch. The new form opens with the source system values pre-filled, and you can change any field before saving.

Delete A System

Deleting an integration system removes the system and its connector links. Do this only when the system is no longer needed in discovery or PII pattern setup.

Tips And Best Practices

- Use names that match the business system, not the database server or environment.
- Link only the connectors that truly belong to that system.

- Keep one active Integration System mapping per connector so discovery runs resolve the correct pattern library.
- Create the integration system before adding PII patterns, so patterns can be scoped correctly.
- If a system does not appear in Data Discovery, check that the selected connector is linked here.
